Introduction to Neural Network

Neural Network: Topology

Neural Network: Forward

Each neuron at layer l recieves inputs from all neuron from the previous layer $l-{\bf 1}$

$$z_k^l = \sum_j w_{kj}^{l-1} a_j^{l-1}$$

The neuron tansfer the input signal z_k^I via a transfer function σ and send as input to to the next layer

$$a_k^l = \sigma(z_k^l)$$

The cost function of the neural network is dependeng on all the zs of neurons in all layers

$$C\left(z_1^l, z_2^l, ... z_k^l(z_1^{l-1}, z_2^{l-1}, z_3^{l-1}, ...), ...\right)$$

Dihui Lai (WUSTL) Lecture07 October 7, 2019 4/12

Neural Network: Activation Functions

Step Function:
$$\sigma(z) = \begin{cases} 0 & \text{for } z < 0 \\ 1 & \text{for } z \geq 0 \end{cases}$$

$$\text{Logistic/Sigmoid: } \sigma(z) = \frac{1}{1 + e^{-z}}$$

$$\text{hyperbolic tangent: } \sigma(z) = \frac{(e^z - e^{-z})}{(e^z + e^{-z})}$$

$$\text{ReLU: } \sigma(z) = \begin{cases} 0 & \text{for } z \leq 0 \\ z & \text{for } z > 0 \end{cases}$$

Optimization: Stochastic Gradient Descent Method

- Update the weights by changing it along the gradient to reduce the cost function
- 2 do one data point at a time

$$w_j \leftarrow w_j - \eta \frac{\partial C^i(w_j)}{\partial w_j}, i = 1, 2, 3, ...n$$

Gradient Descent Method for Linear Regression

Cost function
$$C(\beta) = \sum_{i=1}^{\infty} (y^i - \vec{x}^i \cdot \vec{\beta})^2$$

$$\frac{\partial C}{\partial \beta_j} = \sum_j (\hat{y}^i - y^i) x_j^i$$

The corresponding stochastic gradient methods is

$$\beta_j \leftarrow \beta_j + \epsilon (y^i - \hat{y}^i) x_j^i$$

The update method is quite intuitive considering that β_j is adjusted higher if estimated \hat{y}^i is less than y^i ; adjusted lower if \hat{y}^i is more than y^i

mini-Batch Gradient Descent

Between use the full data set or use 1 single data point to update w, one can choose to update w by calculating gradient using m data points or called a mini-batch.

Dividing the data set to k mini-batch so that km=n. Iterating through k mini-batches is called an epoch

Neural Network: Backpropogation

Neural Network: Backpropogation

The contribution to the cost function from a neuron in layer *I* can be cauculated iteratively as

$$\delta_k^l = \frac{\partial C}{\partial z_k^l} = \sum_m \frac{\partial C}{\partial z_m^{l+1}} \frac{\partial z_m^{l+1}}{\partial z_k^l}$$

$$= \left(\sum_m \frac{\partial C}{\partial z_m^{l+1}} \frac{\partial z_m^{l+1}}{\partial a_k^l}\right) \frac{\partial a_k^l}{\partial z_k^l}$$

$$= \sum_m \delta_m^{l+1} w_{mk}^l \sigma'(z_k^l)$$

The partial derivative of a cost function w.r.t the weight w_{kj}^{l-1} is

$$\frac{\partial C}{\partial w_{kj}^{l-1}} = \frac{\partial C}{\partial z_k^l} \frac{\partial z_k^l}{\partial w_{kj}^{l-1}} = \delta_k^l a_j^{l-1}$$

Training Neural Network

- 1 Define the topology of your neural network: number of layers, number of units in each layer
- $oldsymbol{2}$ initialize the weights w of the network
- 3 calculate the gradient of cost function by calculating δ_l^k against all neurons, backpropogate iteratively
- 4 updates weights of the network along with the gradient
 - batch gradient descent
 - mini-batch gradient descent
 - stochastic gradient descent

Multinomial distribution and multi-class classification

Multinomial distribution: there could be c outcome of an experiment, each of probability p_1 , p_2 , p_3 , ..., p_c and $\sum\limits_{j=1}^c p_j = \mathbf{1}$. If one perform N experiments, the probability of getting x_1 , x_2 , x_3 , ... x_c of each out come can be described as

$$f(x_1, x_2, x_3, ...x_c) = \frac{N!}{x_1! x_2! ... x_c!} p_1^{x_1} p_2^{x_2} ... p_c^{x_c}$$

The likelihood function can be accordingly written as $L=\prod\limits_{i=1}^n\prod\limits_{j=1}^cp_j^{x_j^i}$ The log-likelihood function (a.k.a log-loss) is

$$\ell = \log(L) = \sum_{i=1}^n \sum_{j=1}^c x_j^i \log(p_j)$$
